

Thoughts:
As we create the guidelines will probably
need to modify the section structure

When using a call to action, use a primary or super button to emphasize a link or action. Don't overdo it - each additional button reduces the visual prominence of the call to action.

Lorem ipsum... Each pattern describes a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over, without ever doing it the same way twice.

Examples: updates to the guidelines on a quarterly basis

Description of forms purpose and function

Order and Layout

The most important items in any given form should typically be listed first. This often includes login and contact information like name and email address that can allow the user to come back if they don't complete the form on the first pass.

When your form has a lot of fields, chunk the fields into separate categories. Those categories can then be divided by either separate headers or accordion-style modules depending on the purpose of the form (non-embedded long vs embedded long)

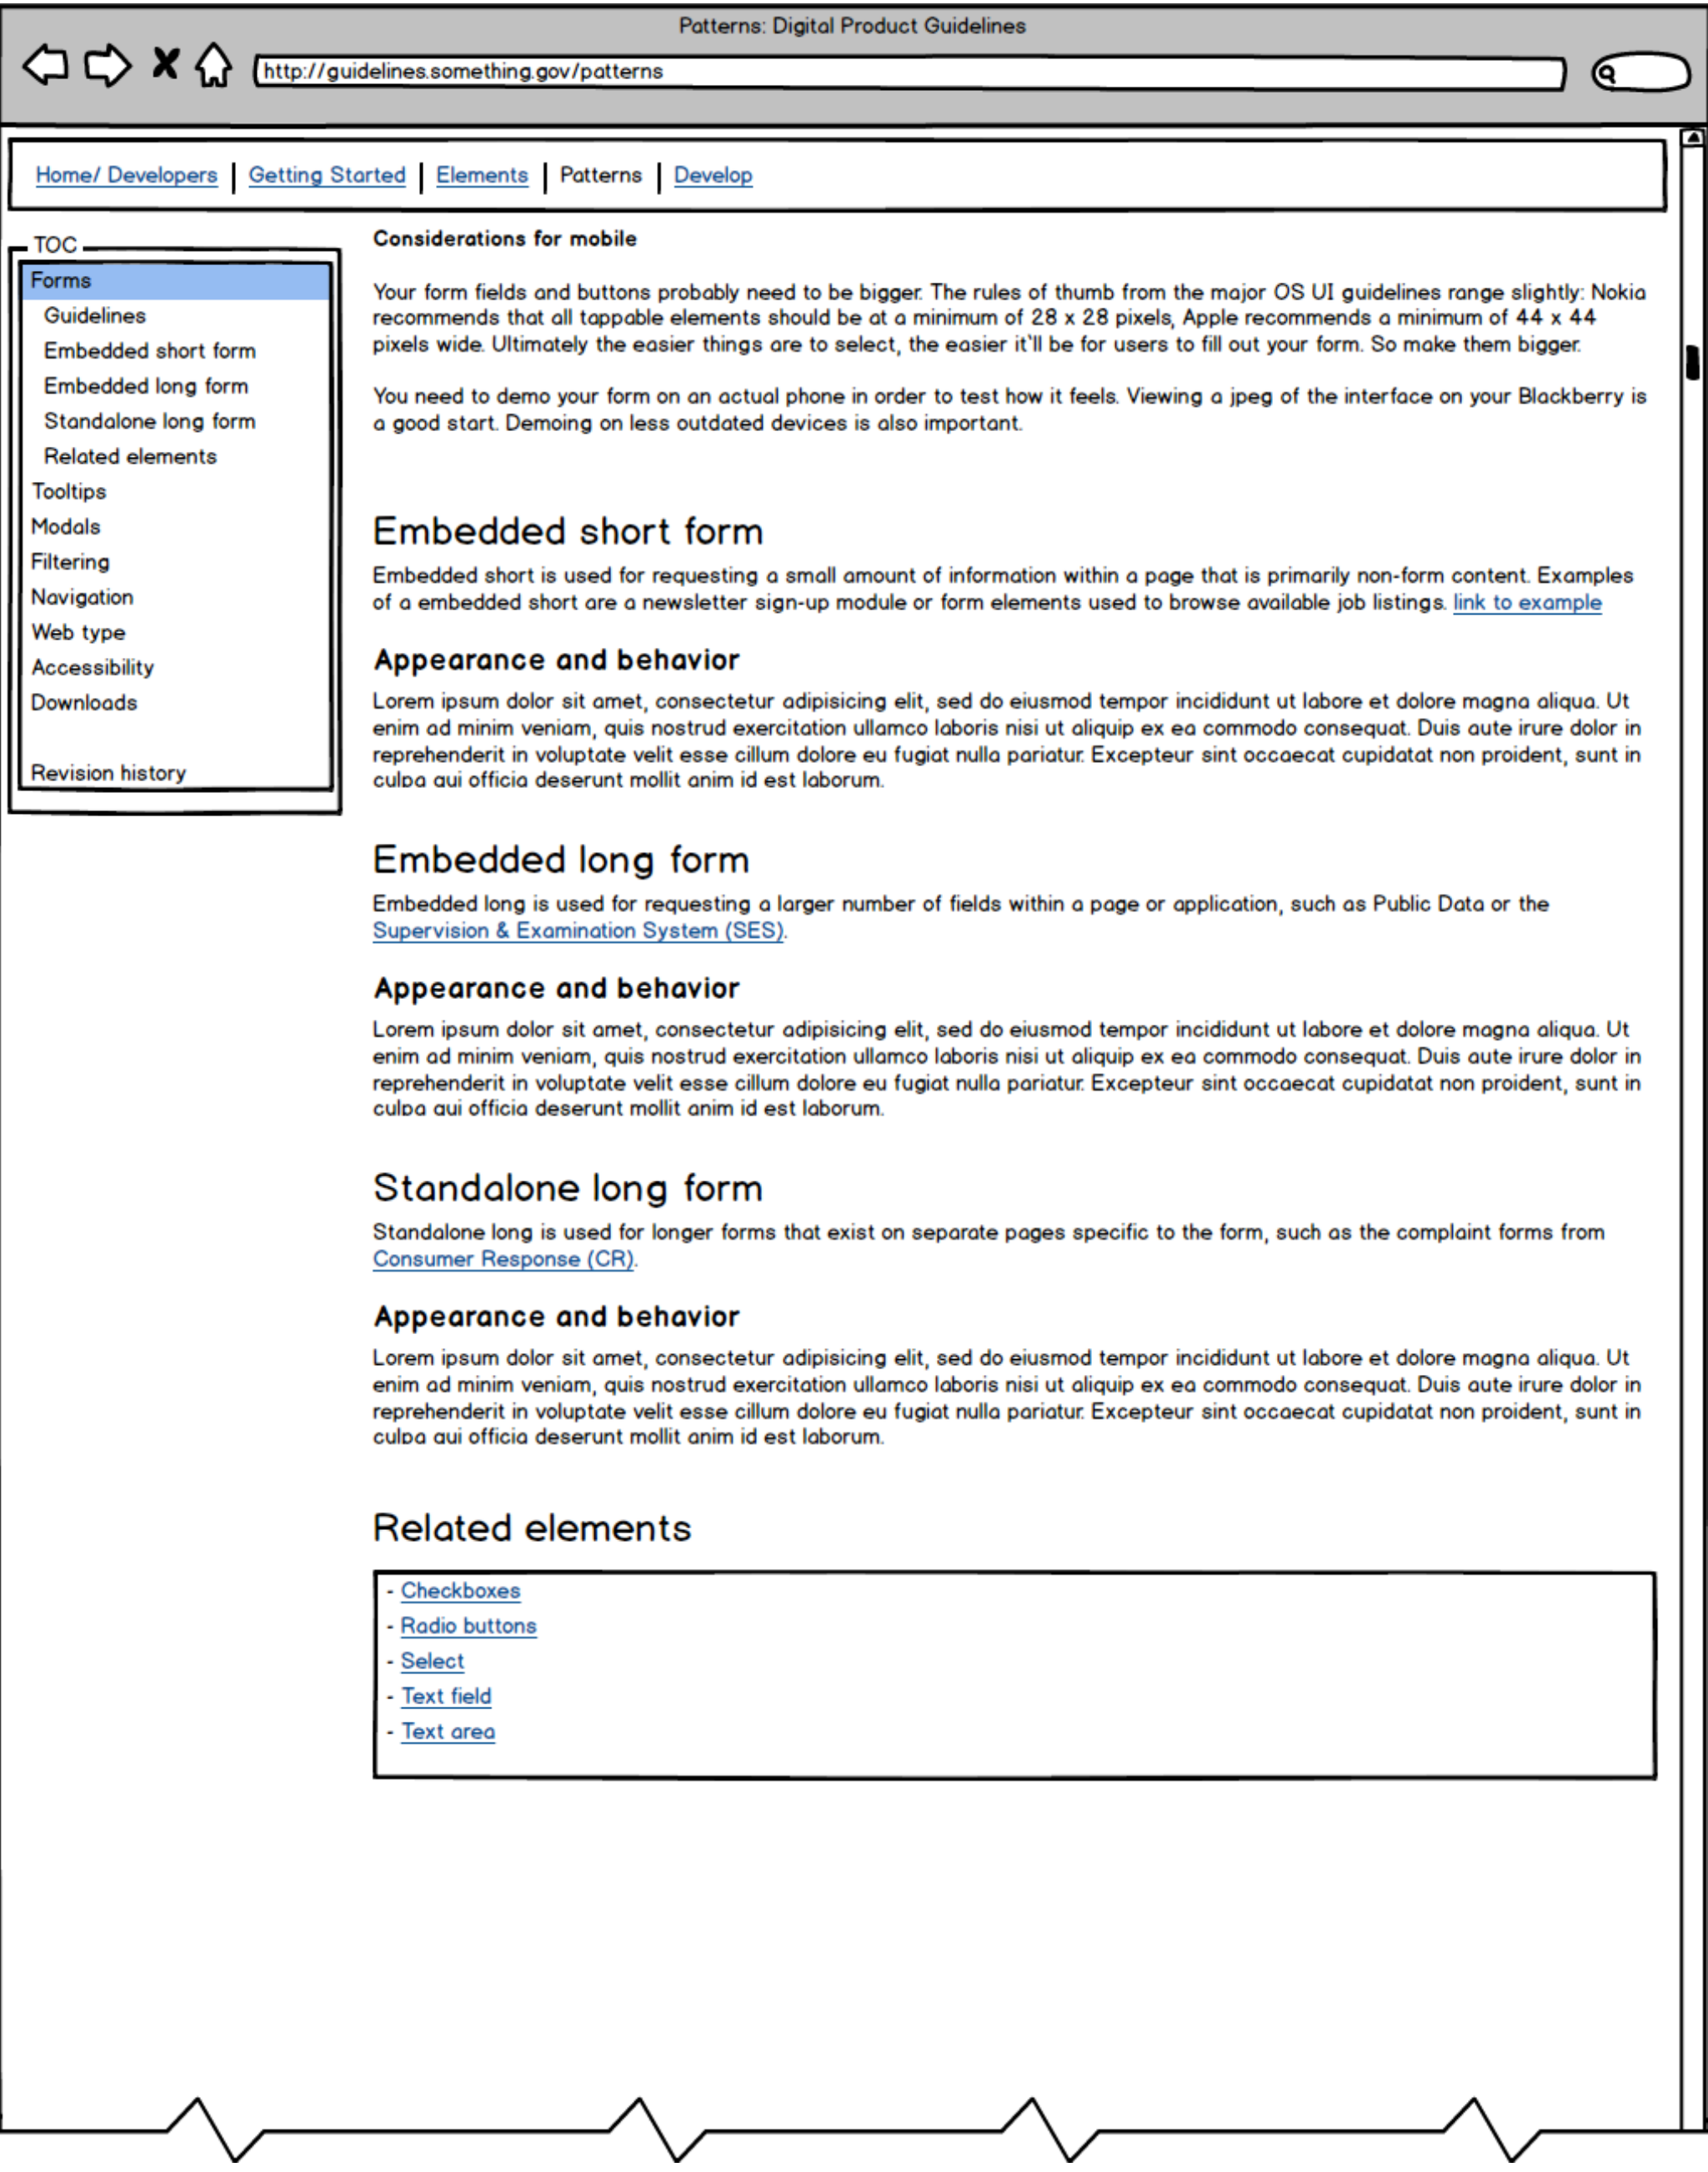

Use progressive disclosure. If there are sections of the form that are optional, consider using a show/hide mechanism like an accordion module. If something is a followup question (e.g., "If you answered yes to the previous question...") don't show it at all until the user has met the condition requiring the follow-up.

Wherever possible, use clear, concise, standard English. Avoid jargon.

Keep labels short and simple. If a longer label is needed, consider phrasing it as a question: "How many chucks did the woodchuck chuck?" rather than "Number of chucks chucked by woodchuck"

Helper text should appear below the text entry field, and provide an example of the correct way to enter text("e.g., 100 Main Street, Anytown, USA"). Do not hide this sort of helper text - it should always be visible, even before the user focuses on the form element (some users won't select a field until they know their answer).

If the most of the fields are required leave them alone and just mark the optional fields as optional. If most of the fields are

Accessibility

The concepts of web accessibility are organized around four guiding principles. These principles lay the foundation for ensuring web content is available for all users. As defined by the W3C, the guidelines are:

Perceivable: Information and user interface components must be presentable to users in ways they can perceive.

Operable: User interface components and navigation must be operable: an interface cannot require interaction that a user cannot perform).

Understandable: Information and the operation of user interface must be understandable.

Robust: Content must be robust enough that it can be interpreted reliably by a wide variety of user agents, including assistive technologies.

Following these guidelines makes web sites and apps more accessible for users with disabilities. It also makes sites and content more usable for everybody, especially users on non-desktop devices. And it helps to ensure forward compatibility, including with devices that are radically different from those in use today.

This document is organized based around these four principles. Note: while this document can function as a checklist – and at times, it will – that isn't the primary purpose. The goal is to foster understanding of why these guidelines are important.

Perceivable

Following these guidelines will ensure the ability to access content on a broad variety of devices. This includes disabled individuals using assistive technology (such as blind users with screen readers, or deaf users needing captions, etc). It also includes users of varying devices, including grayscale screens, mobile devices when muted, devices that can read content to us, etc.

Provide text alternatives for non-text content.

For any content that is not text-based (including images, audio, video, animations, charts, graphs, and so on), provide an alternative version of that content that is text-based. Some techniques for this include:

- Using the <alt> and <title> attributes on images and other graphical elements.
- Using the <title> and <desc> elements in SVG drawings.
- Using fallback text for the <object> element.
- Having descriptive text near the image in the document: for example, the legend for a pie chart might include the percentages of each item.
- Linking to said text in the immediate context of the image or other multimedia.
- Providing transcripts of audio and video recordings.

Note: CAPTCHA does not meet this guideline and should not be used.

There are a few cases where text alternatives are not required (and may in fact be undesirable):

- Form fields that have correctly associated <label> tags should not also have title attributes.
- Images meant to be purely decorative should ideally be included with CSS, but if that is not possible should have blank alt and title attributes.

Provide appropriate alternatives for multimedia

Multimedia such as audio, video, animations and the like will usually require more than just descriptive text. In most cases the timing of text and descriptions in these files is important, and should therefore be included in the alternative versions.

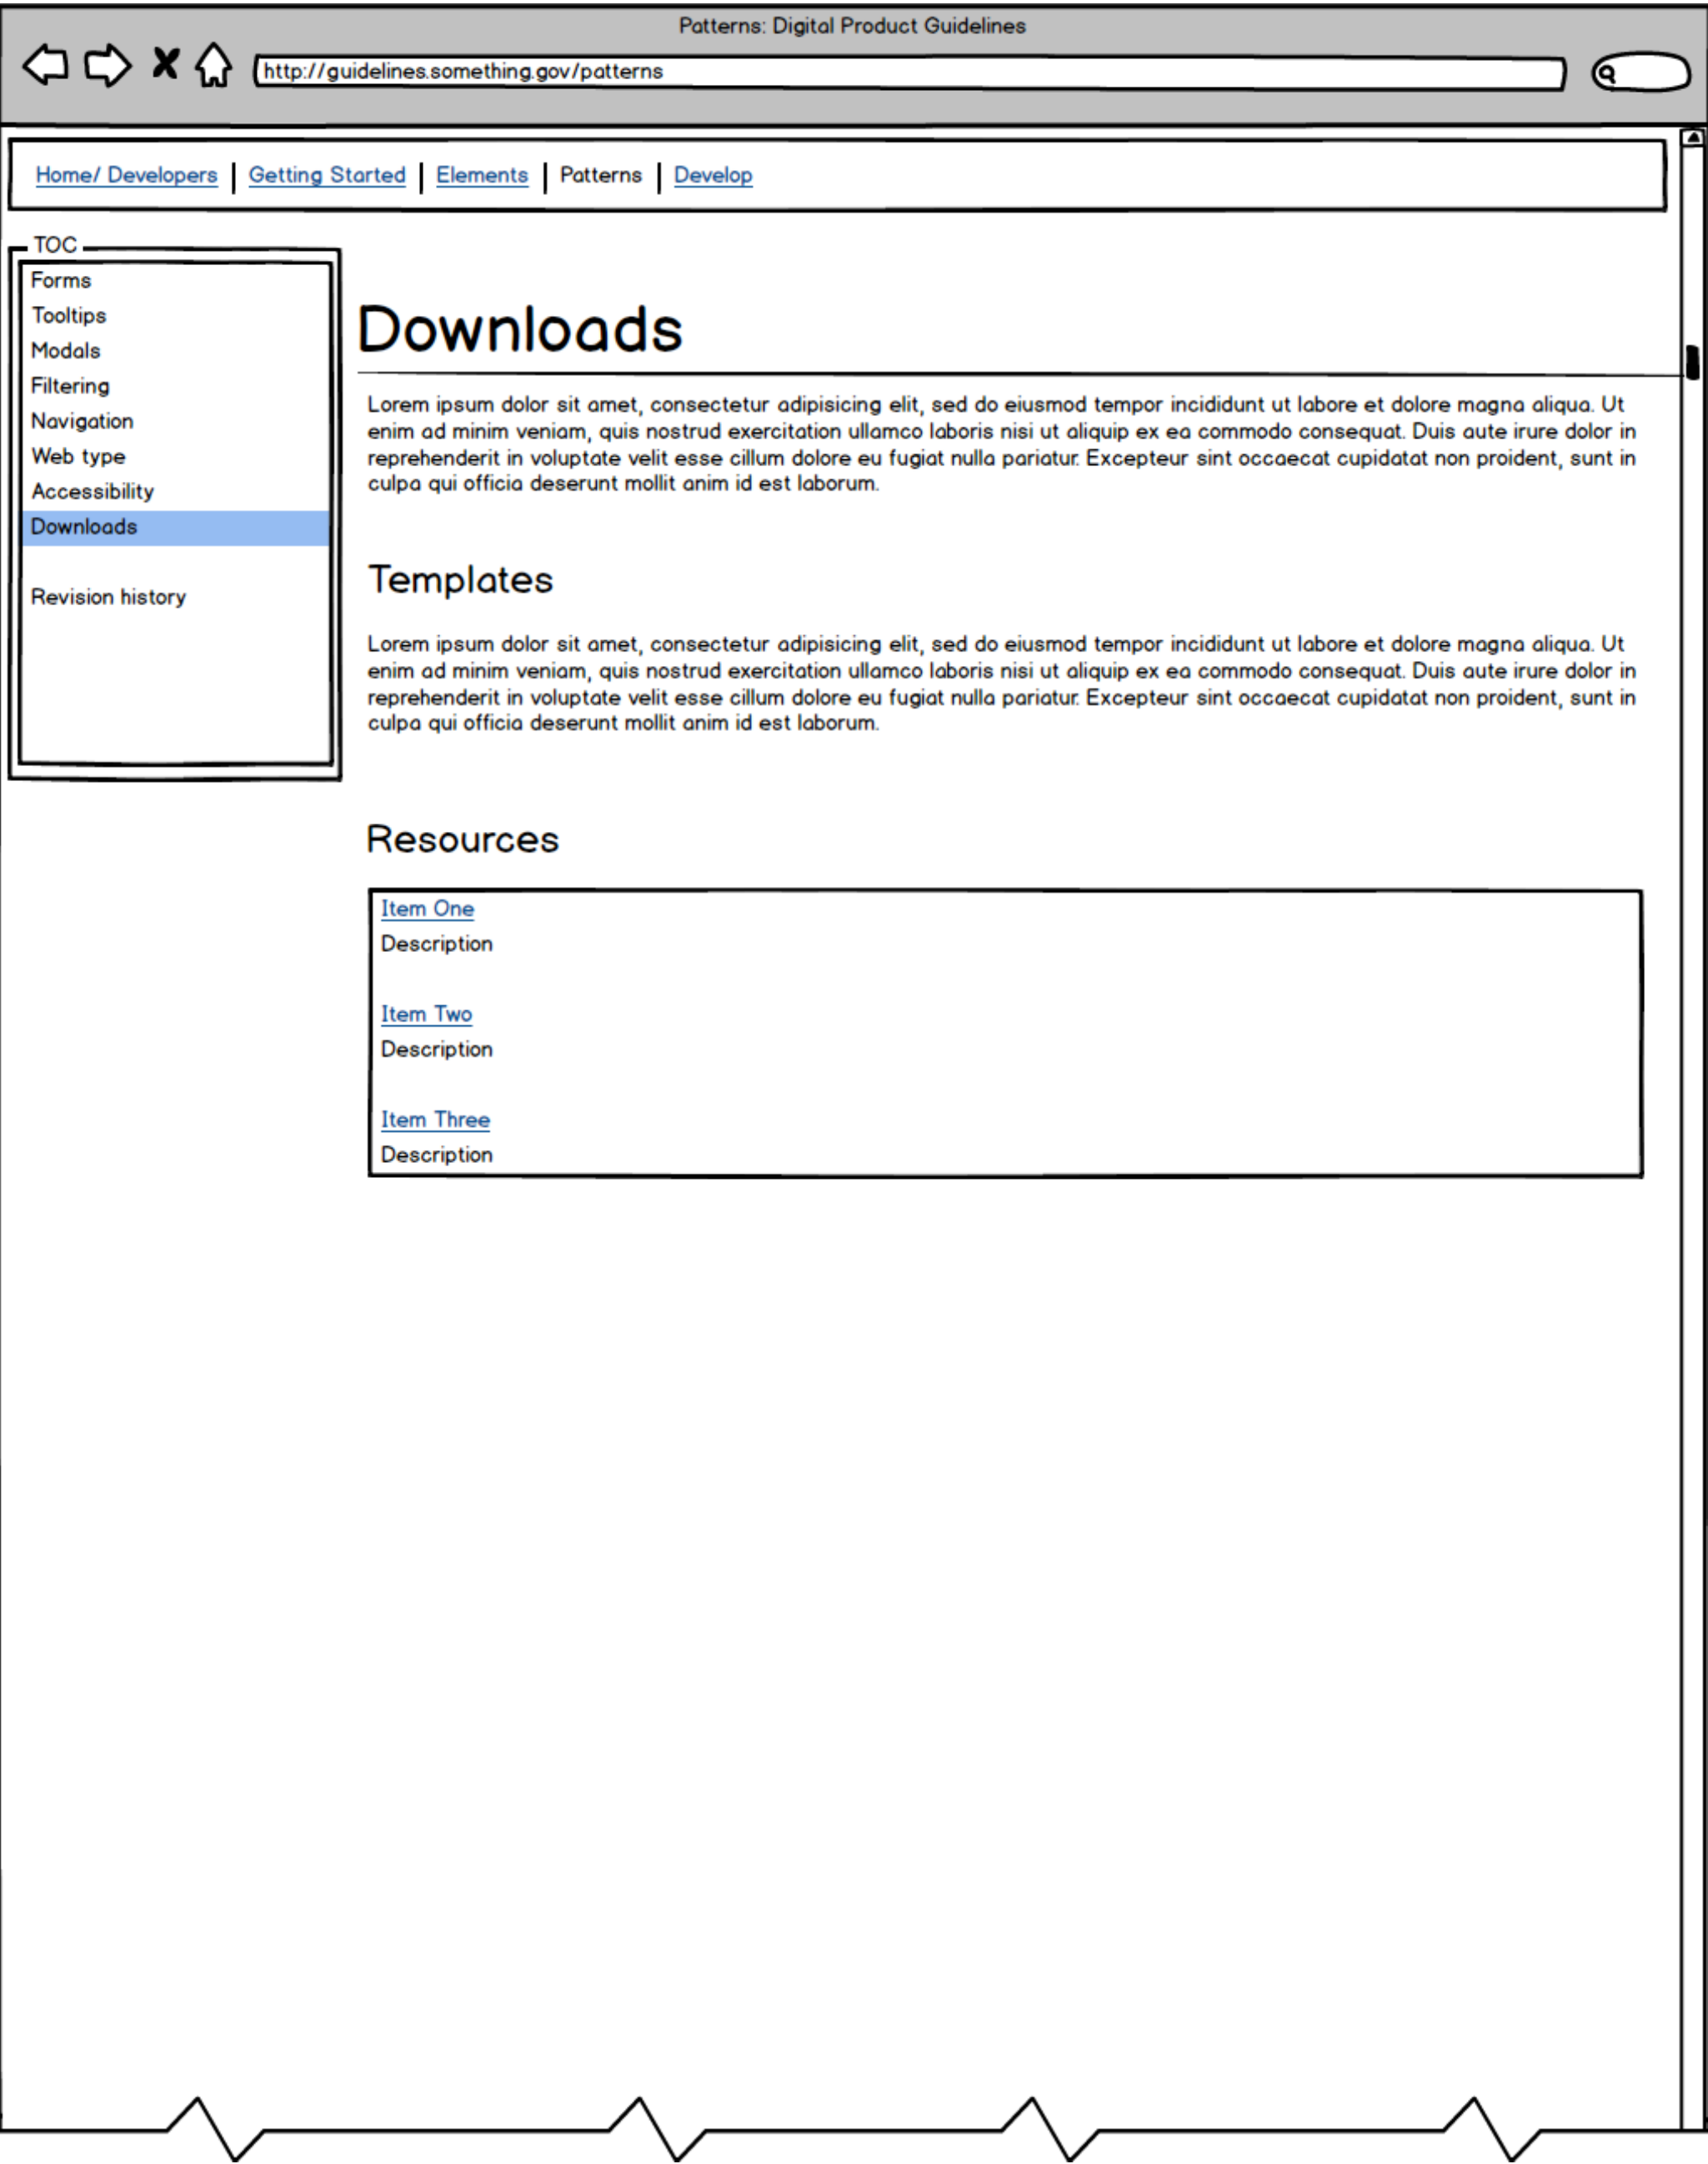

For prerecorded content:

- For audio-only content, provide a transcript that includes both spoken words and descriptions of other sounds.
- For video-only content, provide an audio track with descriptions of the video or a similar description in text.

Combined audio/video content needs to provide alternatives for both the sound and video. There are a few strategies for this:

- Alternatives for sound include closed captions or sign interpretation.
- Alternatives for video include an audio description track or a document similar to a screenplay (which includes dialog, description of sounds, and description of action).

For live content, ideally closed captioning or sign interpretation is available, but in some cases providing the prepared remarks or script alongside the audio/video may be sufficient.

An annotated live demo or static image.

Future thoughts:

- Dimensions? Standards needed for design and development implementation
- Making all examples live demos, with code patterns.
